REVIEW – 2 COMMENTS ADDRESSED

•Clarification: MySQL is not our Big Data storage; it simulates the hospital's existing legacy system.
•The Pipeline Goal: The project demonstrates extracting data *from* limited legacy systems (MySQL) *into* our actual Big Data environment (Hadoop).
•Why Hadoop over MongoDB: MongoDB is an operational NoSQL database (good for live apps). We need a Data Warehouse (Hive on HDFS), which is specifically optimized for massive, historical, batch-analytical queries.

ABSTRACT

Modern hospitals generate millions of machine-generated logs every hour from Wi-Fi routers, servers, and digital medical devices such as MRI and X-ray systems. Due to their volume and velocity, these logs cannot be efficiently analyzed using traditional database systems. This project implements a Hadoop-based Big Data framework to store and analyze these digital footprints. Apache HDFS is used for scalable and fault-tolerant storage, while Apache Hive enables large-scale analytical querying. The system identifies security threats such as brute-force attacks and detects abnormal machine error patterns, helping improve both network security and operational reliability in hospital environments.

INTRODUCTION

The Problem:
Hospitals are high-value targets for cyberattacks such as ransomware. The massive volume of system-generated logs makes manual monitoring and analysis impractical.

The Data:
The project focuses on analyzing system logs, which are automatically generated text files produced by servers, network devices, and medical equipment.

The Solution:
A distributed log analysis framework using Hadoop. Instead of processing logs on a single machine, the system uses a cluster-based approach to detect anomalous patterns across large datasets.

Objective Overview:
To build a scalable pipeline that ingests, cleans, stores, and queries system logs to identify security threats and operational issues.

EXISTING SYSTEM

Current Method:

- Hospitals use traditional **RDBMS** (MySQL/Oracle) for log storage.
- Security relies on **Firewalls** and real-time **IDS**.
- Data retention is short (24–48 hours) due to storage limits.

Major Drawbacks:

- **Storage Limit:** Traditional databases crash or slow down under terabytes of log data.
- **Security Gap:** Firewalls miss "**Low and Slow**" attacks spread over weeks.
- **No Correlation:** Cannot link logs from Wi-Fi, Servers, and MRI machines into one timeline.
- **Reactive Maintenance:** Equipment is fixed only **after failure** because error patterns aren't analysed.

PROPOSED SYSTEM

- Our goal is to build a centralized **Data Warehouse** using Hadoop to store and analyze all hospital machine logs.
- Main purpose is to move from reactive security to **Proactive Forensic Analysis**.
- We are using **Apache Sqoop** to automate the ingestion of data from diverse sources like VPNs, Routers, and MRI machines.
- We deploy the data into **HDFS** to provide a scalable, fault-tolerant storage environment for terabytes of data.
- **Apache Hive** allows us to query 30 days of history at once to detect "low and slow" hacking patterns.
- This solution helps the hospital identify **Predictive Maintenance** needs by analyzing error trends in medical equipment.
- Utilizing this architecture will allow the hospital to maintain a **tamper-proof audit trail** for legal and regulatory compliance

OBJECTIVES

- To store and process large hospital log datasets reliably using HDFS.
- To automate data cleaning and preprocessing using MapReduce.
- To identify security threats and abnormal access patterns via Hive.
- To establish a reliable, end-to-end data pipeline using Sqoop.
- To improve operational reliability by analysing medical equipment error logs.

SOFTWARE REQUIREMENTS

Below are the software requirements for proposed system

- **Virtualization Tool:** Oracle VM VirtualBox.
- **Hadoop Environment:** Cloudera QuickStart VM (CDH - Cloudera Distribution including Hadoop).
- **Guest Operating System:** CentOS (pre-configured inside the Cloudera VM).
- **Core Framework:** Apache Hadoop (HDFS and MapReduce) for storage and processing.
- **Data Ingestion:** Apache Sqoop for importing raw datasets.
- **Data Warehouse:** Apache Hive for writing analytical queries.
- **Relational Database:** MySQL (built into Cloudera) to simulate the hospital's local database.

HARDWARE REQUIREMENTS

The hardware requirements for the proposed system include the following:

- **Processor:** Intel Core i5 / AMD Ryzen 5 (or higher).
- **RAM (Memory):** Minimum 8 GB RAM.
- **Storage Space:** Minimum 50 GB of free disk space.
- **System Architecture:** 64-bit Host Operating System (Windows / Mac / Linux).
- **Network:** Standard Ethernet or Wi-Fi adapter for internal VM networking.
